TABLE 4.1 Classification of Epithelium

Number of Layers				
or Category	Shape of Cells			
Simple (single layer of cells)	Squamous			
	Cuboidal			
	Columnar			
Stratified (more than one layer of cells)	Squamous			
	Nonkeratinized (moist)			
	Keratinized			
	Cuboidal (very rare)			
	Columnar (very rare)			
Pseudostratified (modification of simple epithelium)	Columnar			
Transitional (modification of stratified epithelium)	Roughly cuboidal to columnar when not stretched and squamouslike when stretched

Table 4.2 Simple Epithelium

(a) Simple Squamous Epithelium

Structure: Single layer of flat, often hexagonal cells. The nuclei appear as bumps when viewed as a cross section because the cells are so flat. **Function:** Diffusion, filtration, some protection against friction, secretion, and absorption.

Location: Lining of blood and lymphatic vessels (endothelium) and small ducts, alveoli of the lungs, loop of Henle in kidney tubules, lining of serous membranes (mesothelium), and inner surface of the eardrum.

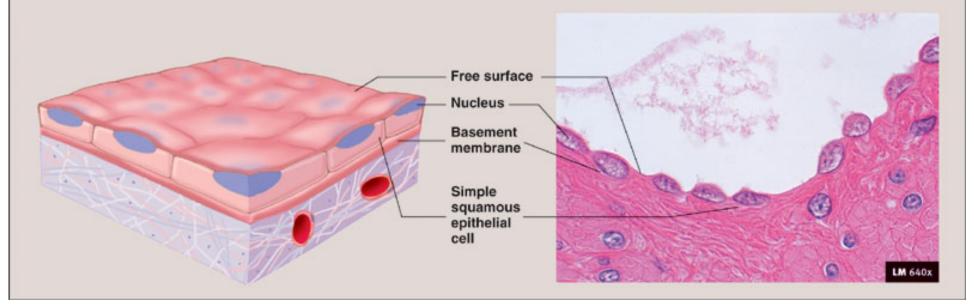

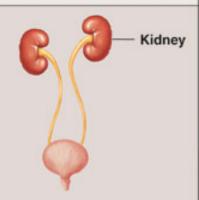

Table 4.2 Simple Epithelium – Continued

(b) Simple Cuboidal Epithelium

Structure: Single layer of cubeshaped cells; some cells have microvilli (kidney tubules) or cilia (terminal bronchioles of the lungs). Function: Active transport and facilitated diffusion result in secretion and absorption by cells of the kidney tubules; secretion by cells of glands and choroid plexus; movement of particles embedded in mucus out of the terminal bronchioles by ciliated cells.

Location: Kidney tubules, glands and their ducts, choroid plexus of the brain, lining of terminal bronchioles of the lungs, and surface of the ovaries.

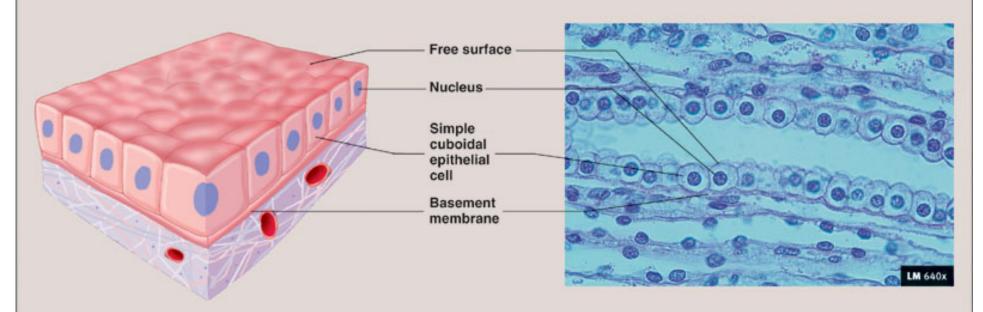

Table 4.2 Simple Epithelium – Continued

(c) Simple Columnar Epithelium

Structure: Single layer of tall, narrow cells. Some cells have cilia (bronchioles of lungs, auditory tubes, uterine tubes, and uterus) or microvilli (intestines).

Function: Movement of particles out of the bronchioles of the lungs by ciliated cells; partially responsible for the movement of the oocyte through the uterine tubes by ciliated cells. Secretion by cells of the glands, the stomach, and the intestine. Absorption by cells of the intestine.

Location: Glands and some ducts, bronchioles of lungs, auditory tubes, uterus, uterine tubes, stomach, intestines, gallbladder, bile ducts, and ventricles of the brain.

Lining of stomach and intestines

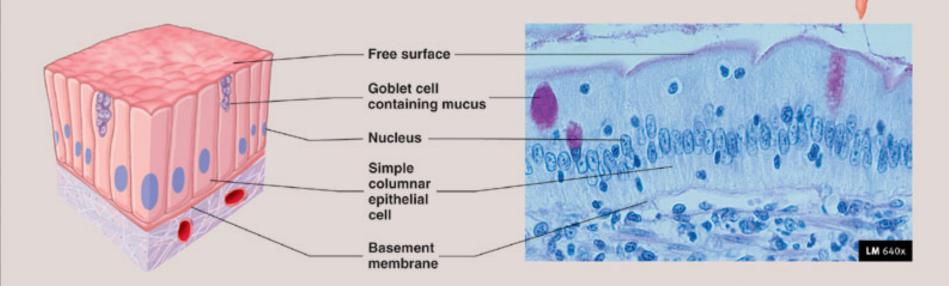

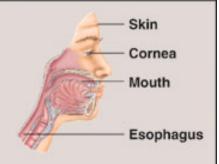

Table 4.3 Stratified Epithelium

(a) Stratified Squamous Epithelium

Structure: Multiple layers of cells that are cuboidal in the basal layer and progressively flattened toward the surface. The epithelium can be nonkeratinized or keratinized. In nonkeratinized stratified squamous epithelium the surface cells retain a nucleus and cytoplasm. In keratinized stratified epithelium, the cytoplasm of cells at the surface is replaced by a protein called keratin, and the cells are dead.

Function: Protection against abrasion, barrier against infection, and prevents loss of water from the body. Location: Keratinized—skin. Nonkeratinized—mouth, throat, larynx, esophagus, anus, vagina, inferior urethra, and cornea.

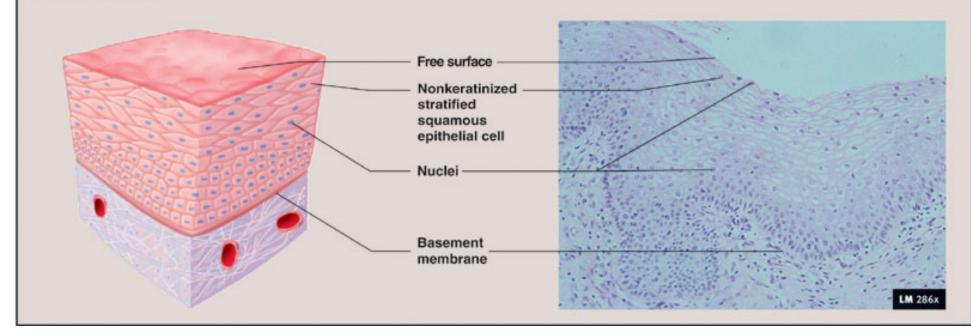

Table 4.3 Stratified Epithelium – Continued (b) Stratified Cuboidal Epithelium Structure: Multiple layers of Function: Secretion, absorption, Location: Sweat gland ducts, ovarian follicular cells, and salivary gland somewhat cube-shaped cells. and protection against infection. ducts. Parotid gland duct Sublingual gland duct Submandibular gland duct Free surface Nucleus Basement membrane Stratified cuboidal epithelial cell

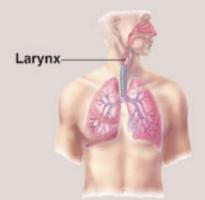

Table 4.3 Stratified Epithelium – Continued

(c) Stratified Columnar Epithelium

Structure: Multiple layers of cells, with tall, thin cells resting on layers of more cuboidal cells. The cells are ciliated in the larynx.

Function: Protection and secretion.

Location: Mammary gland duct, larynx, and a portion of the male urethra.

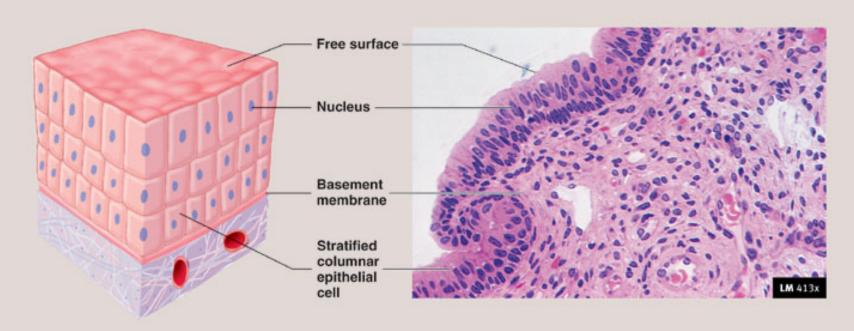

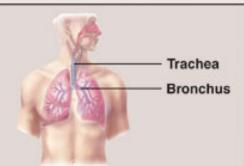

Table 4.4 Pseudostratified Columnar Epithelium and Transitional Epithelium

(a) Pseudostratified Columnar Epithelium

Structure: Single layer of cells; some cells are tall and thin and reach the free surface, and others do not; the nuclei of these cells are at different levels and appear stratified; the cells are almost always ciliated and are associated with goblet cells that secrete mucus onto the free surface.

Function: Synthesize and secrete mucus onto the free surface and move mucus (or fluid) that contains foreign particles over the surface of the free surface and from passages. Location: Lining of nasal cavity, nasal sinuses, auditory tubes, pharynx, trachea, and bronchi of lungs.

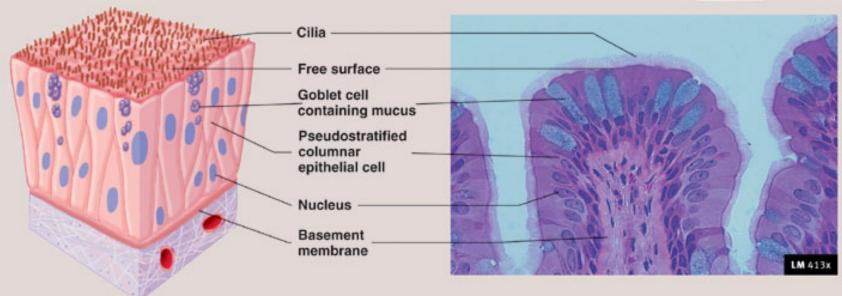

Table 4.4 Pseudostratified Columnar Epithelium and Transitional Epithelium - Continued

(b) Transitional Epithelium

Function: Accommodates Location: Lining of urinary bladder, Structure: Stratified cells that appear cuboidal when the organ or tube is fluctuations in the volume of fluid in ureters, and superior urethra. not stretched and squamous when an organ or tube; protection against the caustic effects of urine. the organ or tube is stretched by fluid. Ureter Free surface Urinary bladder Transitional epithelial cell Urethra Nucleus Basement membrane Free surface Transitional Tissue not stretched epithelial cell Nucleus Basement membrane Tissue stretched

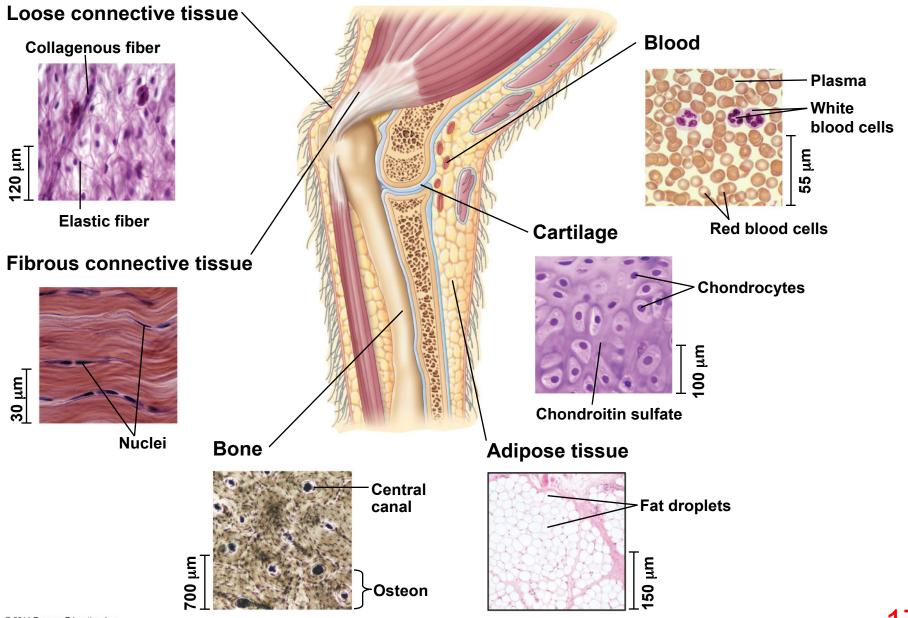

Constituents of Connective Tissues

- 1. Cells
 - A. Blasts
 - **B. Cytes**
 - C. Clasts
- 2. Extracellular Matrix
 - A. Ground Substance
 - **B. Fibers**
 - I. Collagenous
 - II. Elastic
 - III. Reticular

TABLE 4.6 Classification of Connective Tissue

- A. Embryonic connective tissue
 - 1. Mesenchyme
 - 2. Mucous
- B. Adult connective tissue
 - 1. Loose (areolar)
 - 2. Dense
 - a. Dense, regular collagenous
 - b. Dense, regular elastic
 - c. Dense, irregular collagenous
 - d. Dense, irregular elastic
 - 3. Special properties
 - a. Adipose
 - b. Reticular
 - 4. Cartilage
 - a. Hyaline
 - b. Fibrocartilage
 - c. Elastic
 - 5. Bone
 - a. Cancellous
 - b. Compact
 - 6. Blood and hemopoietic tissue

Connective Tissue

© 2011 Pearson Education, Inc.

Table 4.7 Embryonic Connective Tissue

(a) Mesenchyme

Structure: The mesenchymal cells are irregularly shaped. The extracellular matrix is abundant and contains scattered reticular fibers.

Location: Mesenchyme is the embryonic tissue from which connective tissues, as well as other tissues, arise.

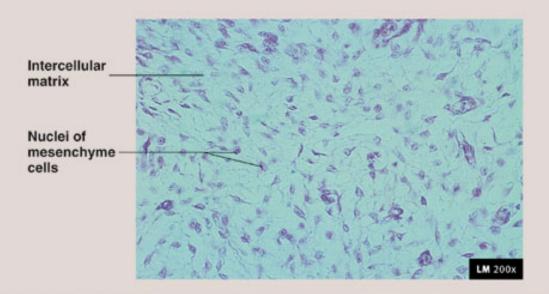

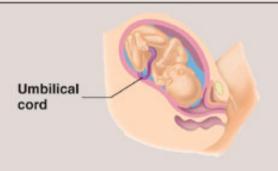

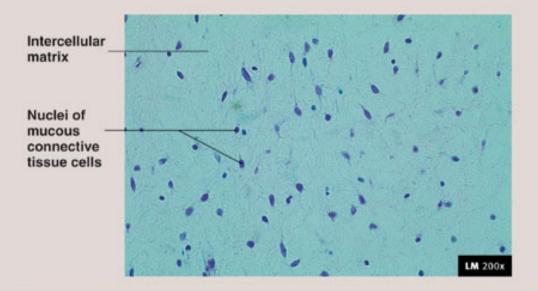

Table 4.7 Embryonic Connective Tissue – Continued

(b) Mucous Connective Tissue

Structure: Mucous tissue is mesenchymal tissue that remains unspecialized. The cells are irregularly shaped. The extracellular matrix is abundant and contains scattered reticular fibers.

Location: Umbilical cord of newborn.

Table 4.8 Loose Connective Tissue Structure: Cells (e.g., fibroblasts, Function: Loose packing, support, and Location: Widely distributed throughout the nourishment for the structures with macrophages, and lymphocytes) body; substance on which epithelial within a fine network of mostly which it is associated. basement membranes rest; packing collagen fibers. Often merges with between glands, muscles, and nerves. Attaches the skin to underlying tissues. denser connective tissue. Elastic Skin Nucleus -**Epidermis** fiber Layer of dermis Loose connective tissue Fat Collagen fiber Muscle

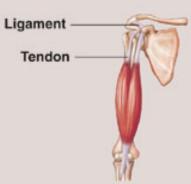

Table 4.9 Dense Connective Tissue

(a) Dense Regular Collagenous Connective Tissue

Structure: Matrix composed of collagen fibers running in somewhat the same direction.

Function: Ability to withstand great pulling forces exerted in the direction of fiber orientation, great tensile strength, and stretch resistance. **Location:** Tendons (attach muscle to bone) and ligaments (attach bones to each other).

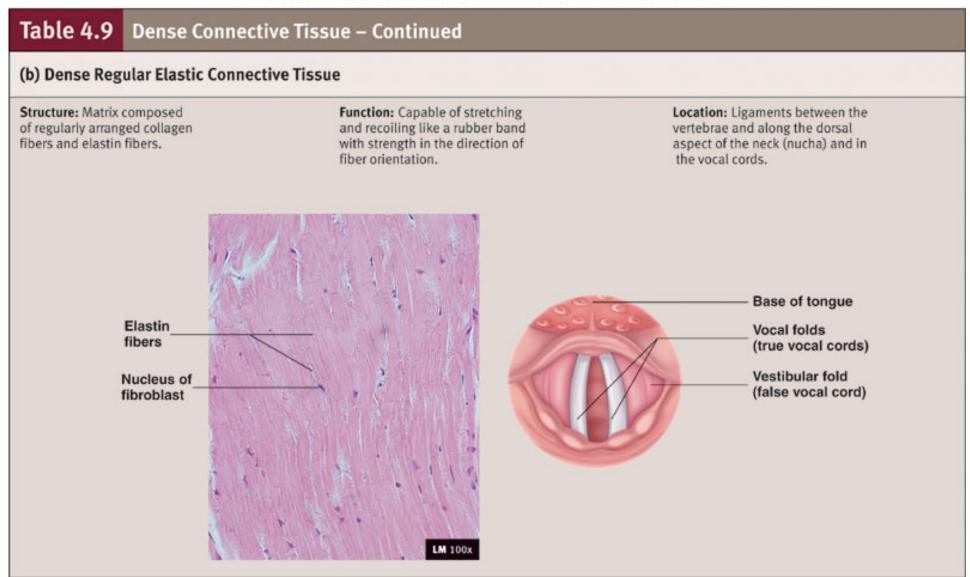

Table 4.9 Dense Connective Tissue - Continued (c) Dense Irregular Collagenous Connective Tissue Structure: Matrix composed of collagen Function: Tensile strength Location: Sheaths: most of the fibers that run in all directions or in capable of withstanding dermis of the skin; organ capsules alternating planes of fibers oriented in a stretching in all directions. and septa; outer covering of body somewhat single direction. tubes. Skin **Epidermis Epidermis** Layer of dermis Loose connective Dense irregular tissue collagenous Fat connective tissue of dermis Muscle

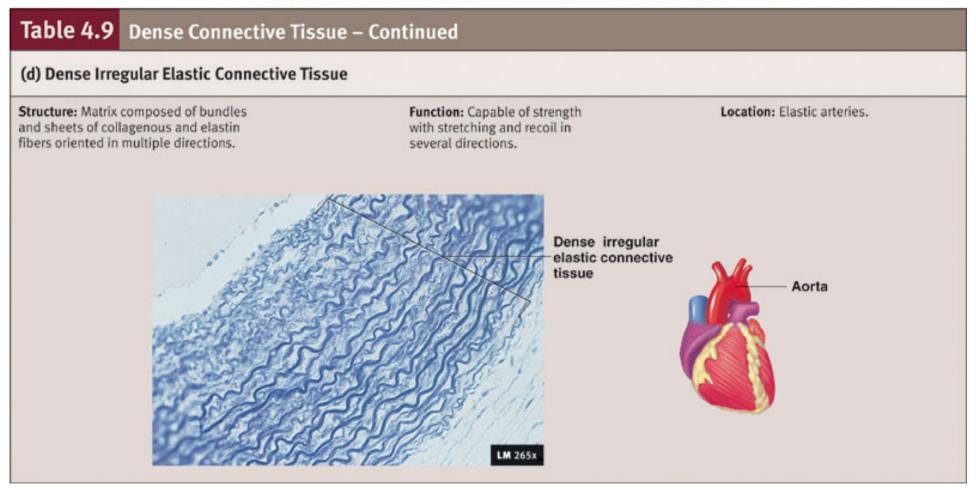

Table 4.10 Connective Tissue with Special Properties

(a) Adipose Tissue

Structure: Little extracellular matrix surrounding cells. The adipocytes, or fat cells, are so full of lipid that the cytoplasm is pushed to the periphery of the cell. Function: Packing material, thermal insulator, energy storage, and protection of organs against injury from being bumped or jarred.

Location: Predominantly in subcutaneous areas, mesenteries, renal pelvis, around kidneys, attached to the surface of the colon, mammary glands, and in loose connective tissue that penetrates into spaces and crevices.

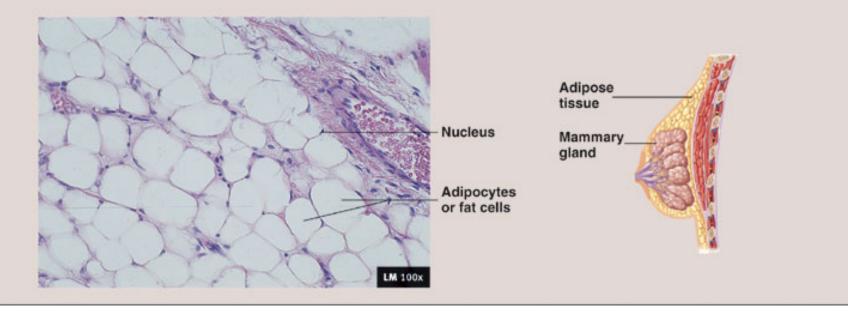

Table 4.10 Connective Tissue with Special Properties - Continued (b) Reticular Tissue Structure: Fine network of reticular Function: Provides a superstructure for Location: Within the lymph nodes, spleen, fibers irregularly arranged. the lymphatic and hemopoietic tissues. and bone marrow. Lymph node Nucleus of lymphocyte Reticular fibers Spleen

Table 4.11 Connective Tissue: Cartilage

(a) Hyaline Cartilage

Structure: Collagen fibers are small and evenly dispersed in the matrix, making the matrix appear transparent. The cartilage cells, or chondrocytes, are found in spaces, or lacunae, within the firm but flexible matrix.

Function: Allows growth of long bones. Provides rigidity with some flexibility in the trachea, bronchi, ribs, and nose. Forms rugged, smooth, yet somewhat flexible articulating surfaces. Forms the embryonic skeleton.

Location: Growing long bones, cartilage rings of the respiratory system, costal cartilage of ribs, nasal cartilage, articulating surface of bones, and the embryonic skeleton.

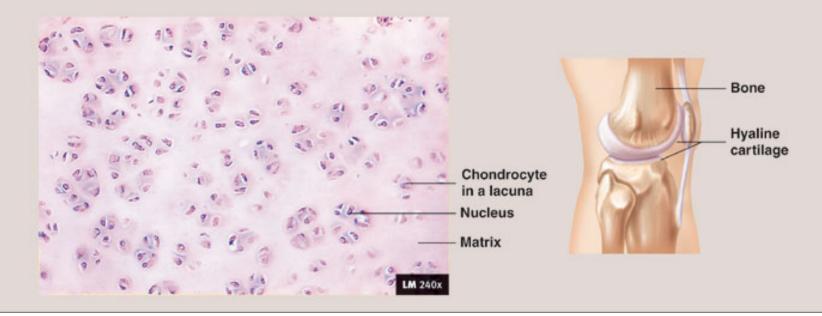

Table 4.11 Connective Tissue: Cartilage – Continued (b) Fibrocartilage Structure: Collagenous fibers similar to Function: Somewhat flexible and capable of Location: Intervertebral disks, symphysis those in hyaline cartilage. The fibers are withstanding considerable pressure. Connects pubis, articular disks (e.g., knee and more numerous than in other cartilages structures subjected to great pressure. temporomandibular [jaw] joints). and are arranged in thick bundles Chondrocyte in lacuna Nucleus Intervertebral disk Collagen fibers in matrix LM 240x

Table 4.11 Connective Tissue: Cartilage – Continued

(c) Elastic Cartilage

Structure: Similar to hyaline cartilage, but matrix also contains elastin fibers.

Function: Provides rigidity with even more flexibility than hyaline cartilage because elastic fibers return to their original shape after being stretched. **Location:** External ear, epiglottis, and auditory tubes.

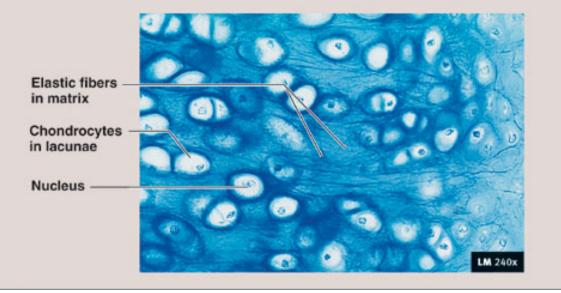

Table 4.12 Connective Tissue: Bones

(a) Cancellous Bone

Structure: Latticelike network of scaffolding characterized by trabeculae with large spaces between them filled with hemopoietic tissue. The osteocytes, or bone cells, are located within lacunae in the trabeculae.

Function: Acts as a scaffolding to provide strength and support without the greater weight of compact bone.

Location: In the interior of the bones of the skull, vertebrae, sternum, and pelvis; also found in the ends of the long bones.

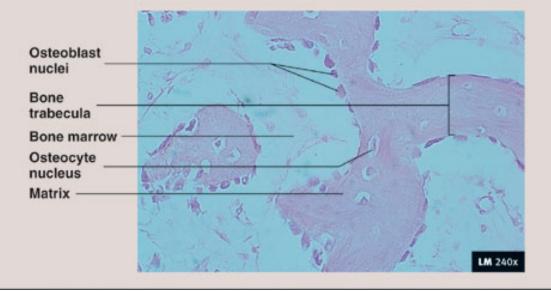

Table 4.12 Connective Tissue: Bones – Continued

(b) Compact Bone

Structure: Hard, bony matrix predominates. Many osteocytes (not seen in this bone preparation) are located within lacunae that are distributed in a circular fashion around the central canals. Small passageways connect adjacent lacunae.

Function: Provides great strength and support. Forms a solid outer shell on bones that keeps them from being easily broken or punctured.

Location: Outer portions of all bones and the shafts of long bones.

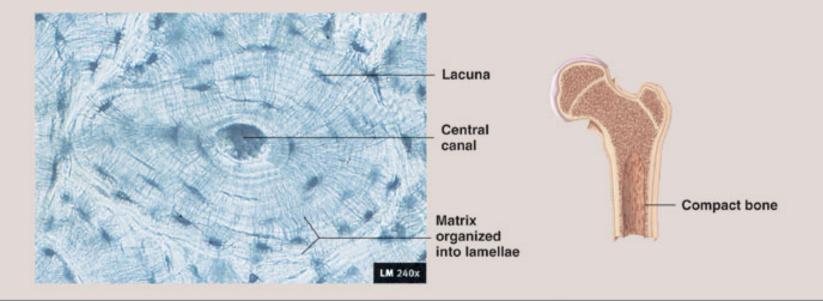

Table 4.13 Connective Tissue: Blood and Hemopoietic Tissue

(a) Blood

Structure: Blood cells and a fluid matrix.

Function: Transports oxygen, carbon dioxide, hormones, nutrients, waste products, and other substances. Protects the body from infections and is involved in temperature regulation.

Location: Within the blood vessels. Produced by the hemopoietic tissues. White blood cells frequently leave the blood vessels and enter the interstitial spaces.

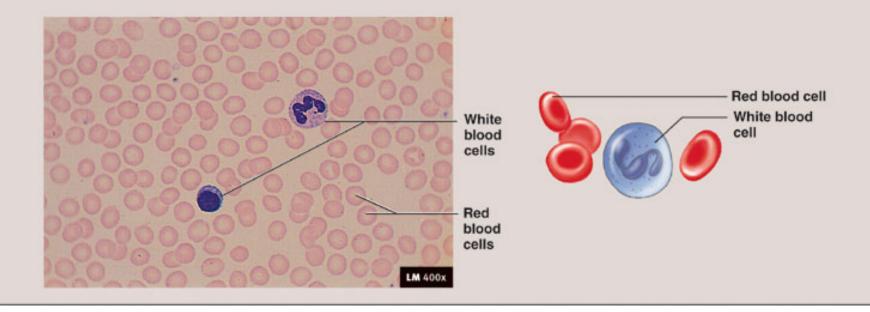

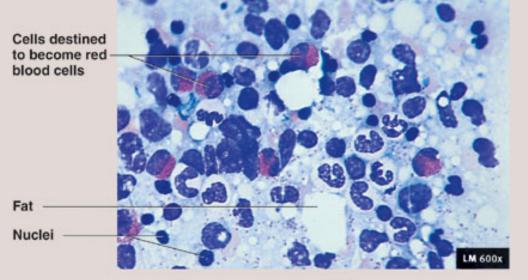

Table 4.13 Connective Tissue: Blood and Hemopoietic Tissue - Continued

(b) Bone Marrow

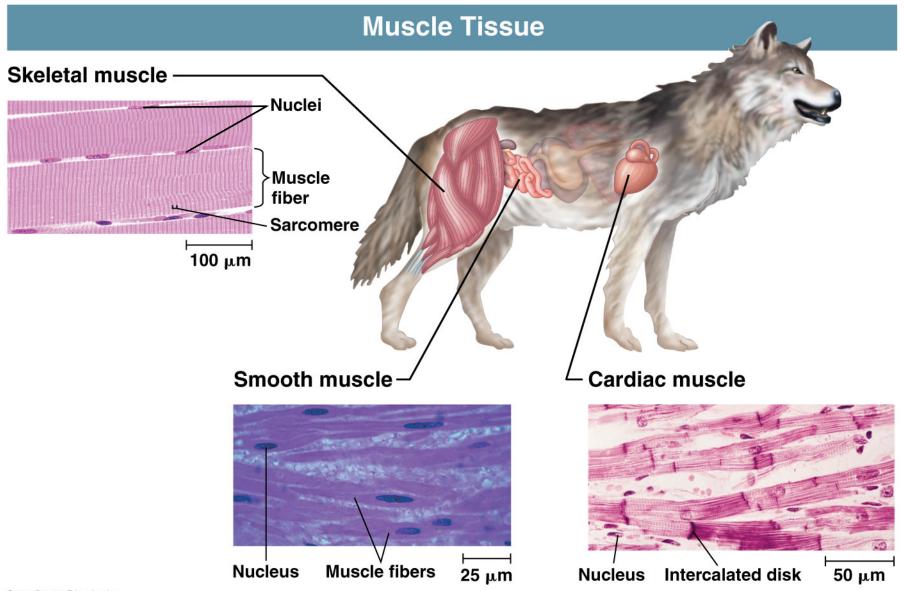

Structure: Reticular framework with numerous blood-forming cells (red marrow).

Function: Production of new blood cells (red marrow); lipid storage (yellow marrow).

Location: Within marrow cavities of bone. Two types: yellow marrow (mostly adipose tissue) in the shafts of long bones; and red marrow (hemopoietic or blood-forming tissue) in the ends of long bones and in short, flat, and irregularly shaped bones.

TABLE 4.14	Comparison of Muscle Types		
	Skeletal Muscle	Cardiac Muscle	Smooth Muscle
Location	Attached to bones	Heart	Walls of hollow organs, blood vessels, eyes, glands, skin
Cell Shape	Very long, cylindrical cells (1–4 cm and may extend the entire length of the muscle; 10–100 μm in diameter)	Cylindrical cells that branch (100–500 µm in length; 12–20 µm in diameter)	Spindle-shaped cells (15–200 μm in length; 5–8 μm in diameter)
Nucleus	Multinucleated, peripherally located	Single, centrally located	Single, centrally located
Striations	Yes	Yes	No
Control	Voluntary (conscious)	Involuntary (unconscious)	Involuntary (unconscious)
Ability to Contract Spontaneously	No	Yes	Yes
Function	Body movement	Contraction provides the major force for moving blood through the blood vessels.	Movement of food through the digestive tract, emptying of the urinary bladder, regulation of blood vessel diameter, change in pupil size, contraction of many gland ducts, movement of hair, and many more functions
Special Features		Branching fibers, intercalated disks containing gap junctions joining the cells to each other	Gap junctions
