Types of Tissue

- Epithelial Tissue
- Connective Tissue
- Muscle Tissue
- Nervous Tissue

1

Properties of Epithelia

- Cellularity
- Polarity
- Avascularity
- Regeneration

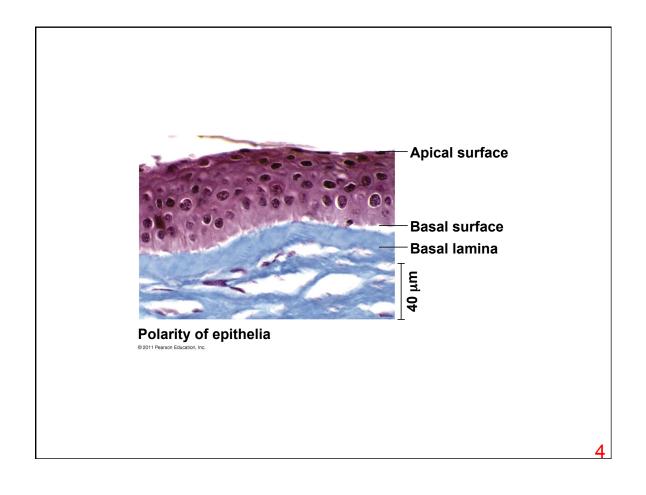

TABLE 4.1 Classification of Epithelium		
Number of Layers or Category	Shape of Cells	
Simple (single layer of cells)	Squamous	
	Cuboidal	
	Columnar	
Stratified (more than one	Squamous	
layer of cells)	Nonkeratinized (moist)	
	Keratinized	
	Cuboidal (very rare)	
	Columnar (very rare)	
Pseudostratified (modification of simple epithelium)	Columnar	
Transitional (modification of stratified epithelium)	Roughly cuboidal to columnar when not stretched and squamouslike when stretched	

S

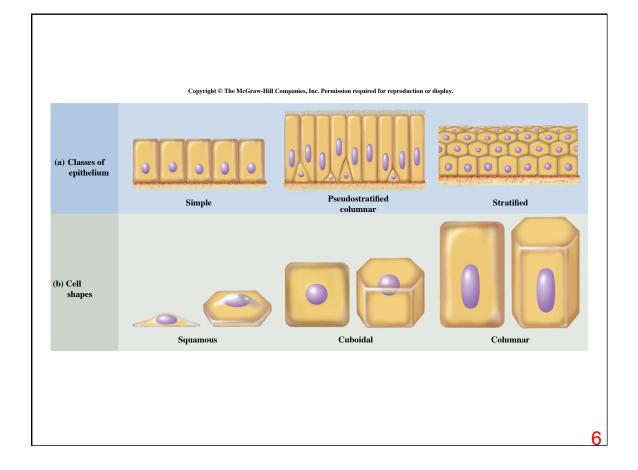

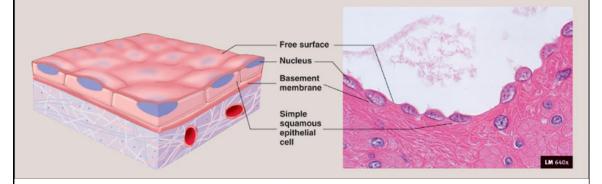

Table 4.2 Simple Epithelium

(a) Simple Squamous Epithelium

Structure: Single layer of flat, often hexagonal cells. The nuclei appear as bumps when viewed as a cross section because the cells are so flat. Function: Diffusion, filtration, some protection against friction, secretion, and absorption.

Location: Lining of blood and lymphatic vessels (endothelium) and small ducts, alveoli of the lungs, loop of Henle in kidney tubules, lining of serous membranes (mesothelium), and inner surface of the eardrum.

7

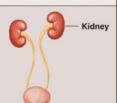

Table 4.2 Simple Epithelium – Continued

(b) Simple Cuboidal Epithelium

Structure: Single layer of cubeshaped cells; some cells have microvilli (kidney tubules) or cilia (terminal bronchioles of the lungs). Function: Active transport and facilitated diffusion result in secretion and absorption by cells of the kidney tubules; secretion by cells of glands and choroid plexus; movement of particles embedded in mucus out of the terminal bronchioles by ciliated cells.

Location: Kidney tubules, glands and their ducts, choroid plexus of the brain, lining of terminal bronchioles of the lungs, and surface of the ovaries.

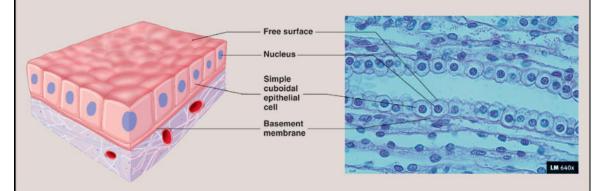

Table 4.2 Simple Epithelium – Continued

(c) Simple Columnar Epithelium

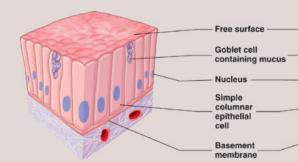

Structure: Single layer of tall, narrow cells. Some cells have cilia (bronchioles of lungs, auditory tubes, uterine tubes, and uterus) or microvilli (intestines).

Function: Movement of particles out of the bronchioles of the lungs by ciliated cells; partially responsible for the movement of the oocyte through the uterine tubes by ciliated cells. Secretion by cells of the glands, the stomach, and the intestine. Absorption by cells of the intestine.

Location: Glands and some ducts, bronchioles of lungs, auditory tubes, uterus, uterine tubes, stomach, intestines, gallbladder, bile ducts, and ventricles of the brain.

Lining of stomach and intestines

Table 4.3 Stratified Epithelium

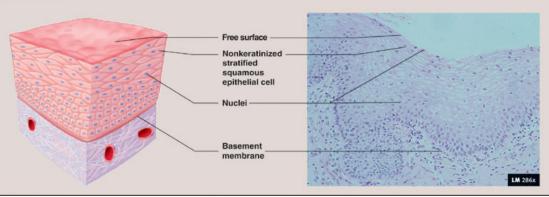

(a) Stratified Squamous Epithelium

Structure: Multiple layers of cells that are cuboidal in the basal layer and progressively flattened toward the surface. The epithelium can be nonkeratinized or keratinized. In nonkeratinized stratified squamous epithelium the surface cells retain a nucleus and cytoplasm. In keratinized stratified epithelium, the cytoplasm of cells at the surface is replaced by a protein called keratin, and the cells are dead.

Function: Protection against abrasion, barrier against infection, and prevents loss of water from the

Location: Keratinized—skin. Nonkeratinized—mouth, throat, larynx, esophagus, anus, vagina, inferior urethra, and cornea.

<u>11</u>

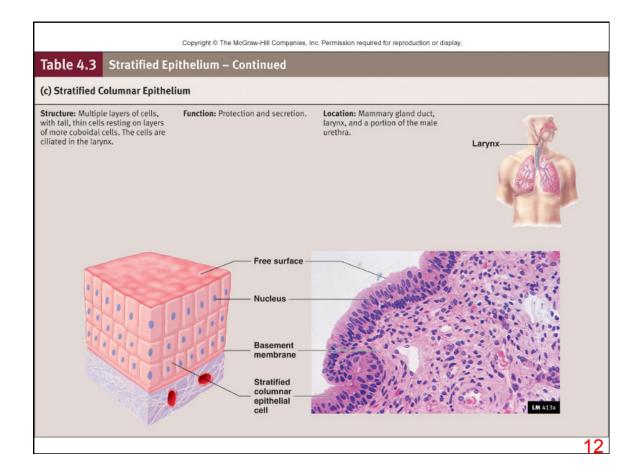

Table 4.4 Pseudostratified Columnar Epithelium and Transitional Epithelium

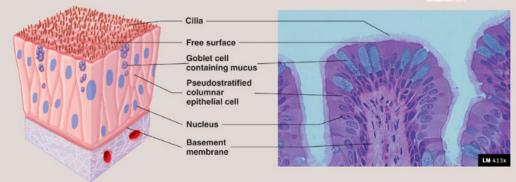

(a) Pseudostratified Columnar Epithelium

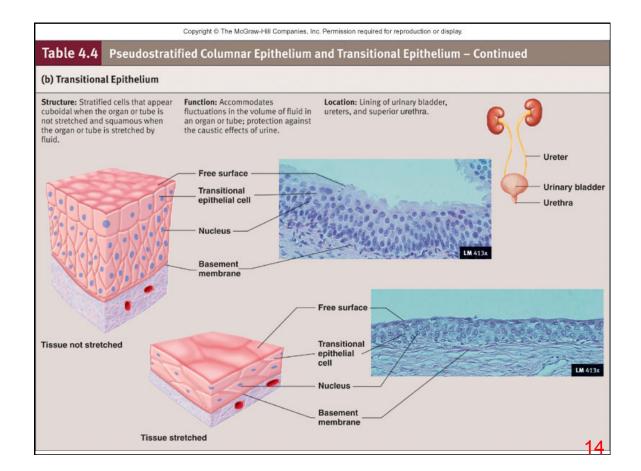

Structure: Single layer of cells; some cells are tall and thin and reach the free surface, and others do not; the nuclei of these cells are at different levels and appear stratified; the cells are almost always ciliated and are associated with goblet cells that secrete mucus onto the free surface.

Function: Synthesize and secrete mucus onto the free surface and move mucus (or fluid) that contains foreign particles over the surface of the free surface and from passages.

Location: Lining of nasal cavity, nasal sinuses, auditory tubes, pharynx, trachea, and bronchi of lungs.

Constituents of Connective Tissues

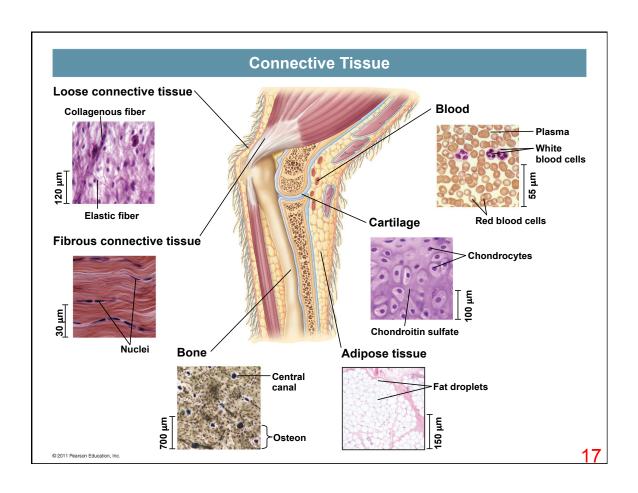

- 1. Cells
 - A. Blasts
 - **B.**Cytes
 - C. Clasts
- 2. Extracellular Matrix
 - **A. Ground Substance**
 - **B. Fibers**
 - I. Collagenous
 - II. Elastic
 - III. Reticular

TABLE 4.6 Classification of Connective

- A. Embryonic connective tissue
 - 1. Mesenchyme
 - 2. Mucous
- B. Adult connective tissue
 - 1. Loose (areolar)
 - 2. Dense
 - a. Dense, regular collagenous
 - b. Dense, regular elastic
 - c. Dense, irregular collagenous
 - d. Dense, irregular elastic
 - 3. Special properties
 - a. Adipose
 - b. Reticular
 - 4. Cartilage
 - a. Hyaline
 - b. Fibrocartilage
 - c. Elastic
 - 5. Bone
 - a. Cancellous
 - b. Compact
 - 6. Blood and hemopoietic tissue

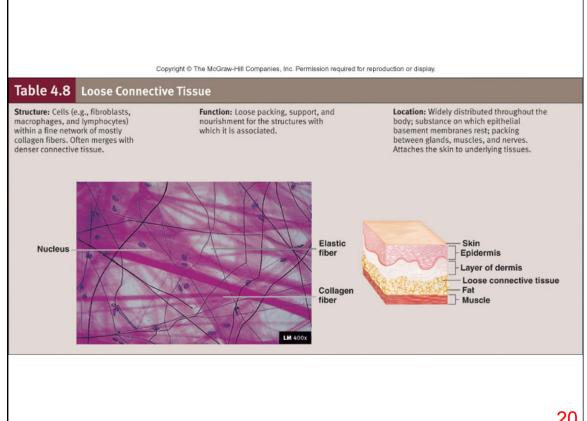

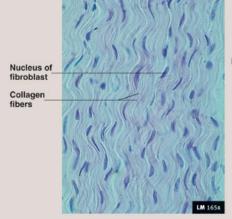

Table 4.9 Dense Connective Tissue

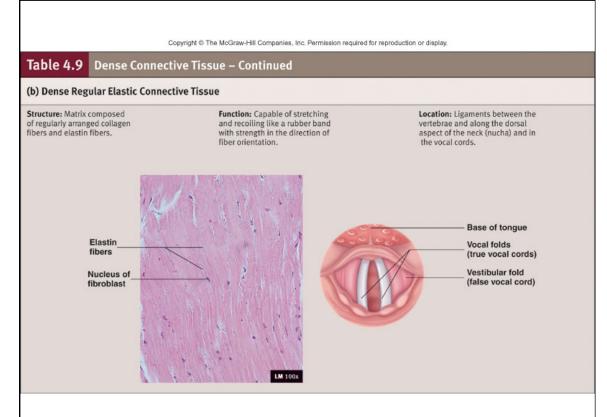

(a) Dense Regular Collagenous Connective Tissue

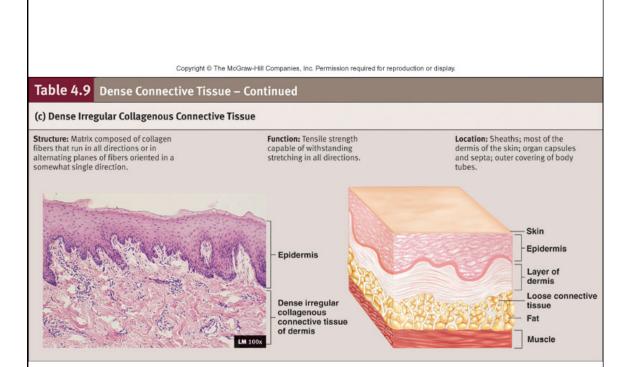

Structure: Matrix composed of collagen fibers running in somewhat the same direction.

Function: Ability to withstand great pulling forces exerted in the direction of fiber orientation, great tensile strength, and stretch resistance. **Location:** Tendons (attach muscle to bone) and ligaments (attach bones to each other).

Tendon Tendon

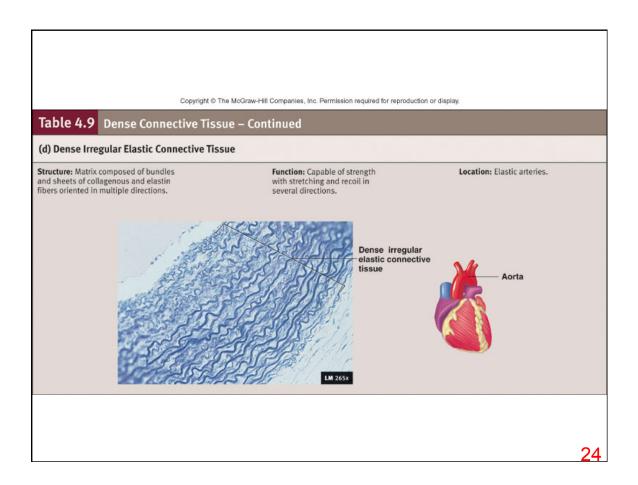

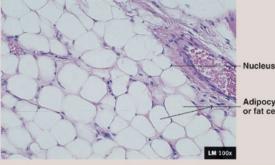

Table 4.10 Connective Tissue with Special Properties

(a) Adipose Tissue

Structure: Little extracellular matrix surrounding cells. The adipocytes, or fat cells, are so full of lipid that the cytoplasm is pushed to the periphery of the cell.

Function: Packing material, thermal insulator, energy storage, and protection of organs against injury from being bumped or jarred. Location: Predominantly in subcutaneous areas, mesenteries, renal pelvis, around kidneys, attached to the surface of the colon, mammary glands, and in loose connective tissue that penetrates into spaces and crevices.

Adipocytes or fat cells

Adipose tissue Mammary gland

Table 4.10 Connective Tissue with Special Properties - Continued

(b) Reticular Tissue

Structure: Fine network of reticular fibers irregularly arranged.

Function: Provides a superstructure for the lymphatic and hemopoietic tissues.

Location: Within the lymph nodes, spleen,

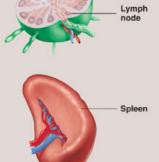

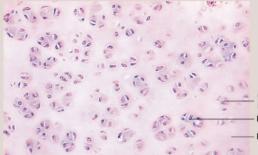

Table 4.11 Connective Tissue: Cartilage

(a) Hyaline Cartilage

Structure: Collagen fibers are small and evenly dispersed in the matrix, making the matrix appear transparent. The cartilage cells, or chondrocytes, are found in spaces, or lacunae, within the firm but flexible matrix.

Function: Allows growth of long bones. Provides rigidity with some flexibility in the trachea, bronchi, ribs, and nose. Forms rugged, smooth, yet somewhat flexible articulating surfaces. Forms the embryonic skeleton.

Location: Growing long bones, cartilage rings of the respiratory system, costal cartilage of ribs, nasal cartilage, articulating surface of bones, and the embryonic skeleton.

Chondrocyte in a lacuna Nucleus Matrix

Table 4.11 Connective Tissue: Cartilage - Continued

(b) Fibrocartilage

Structure: Collagenous fibers similar to those in hyaline cartilage. The fibers are more numerous than in other cartilages and are arranged in thick bundles

Function: Somewhat flexible and capable of withstanding considerable pressure. Connects structures subjected to great pressure.

Location: Intervertebral disks, symphysis pubis, articular disks (e.g., knee and temporomandibular [jaw] joints).

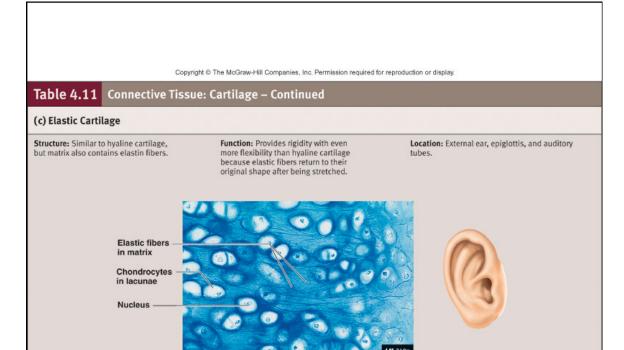

Chondrocyte in lacuna Nucleus

> Collagen fibers in matrix

disk

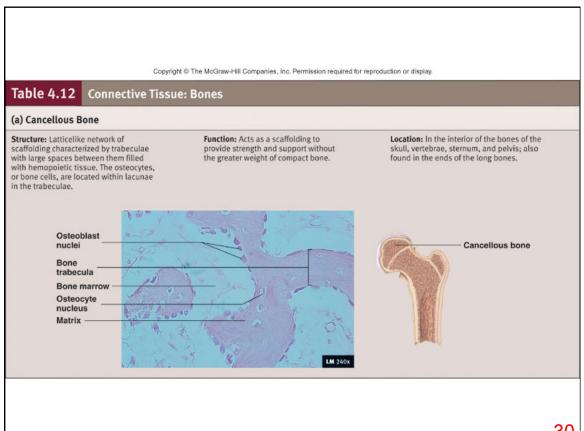

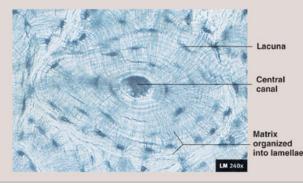

Table 4.12 Connective Tissue: Bones - Continued

(b) Compact Bone

Structure: Hard, bony matrix predominates. Many osteocytes (not seen in this bone preparation) are located within lacunae that are distributed in a circular fashion around the central canals. Small passageways connect adjacent lacunae.

Function: Provides great strength and support. Forms a solid outer shell on bones that keeps them from being easily broken or punctured.

Location: Outer portions of all bones and the shafts of long bones.

Table 4.13 Connective Tissue: Blood and Hemopoietic Tissue

(a) Blood

Structure: Blood cells and a fluid

Function: Transports oxygen, carbon dioxide, hormones, nutrients, waste products, and other substances. Protects the body from infections and is involved in temperature regulation.

Location: Within the blood vessels. Produced by the hemopoletic tissues. White blood cells frequently leave the blood vessels and enter the interstitial spaces.

Red blood cell
White blood
cell

Table 4.13 Connective Tissue: Blood and Hemopoietic Tissue – Continued (b) Bone Marrow Structure: Reticular framework with numerous blood-forming cells (red marrow). Function: Production of new blood cells (red marrow). Function: Production of new blood cells (red marrow). Function: Production of new blood cells (red types: yellow marrow (mostly adipose tissue) in the shafts of long bones; and red marrow (hemopoietic or blood-forming tissue) in the ends of long bones and in short, flat, and irregularly shaped bones.

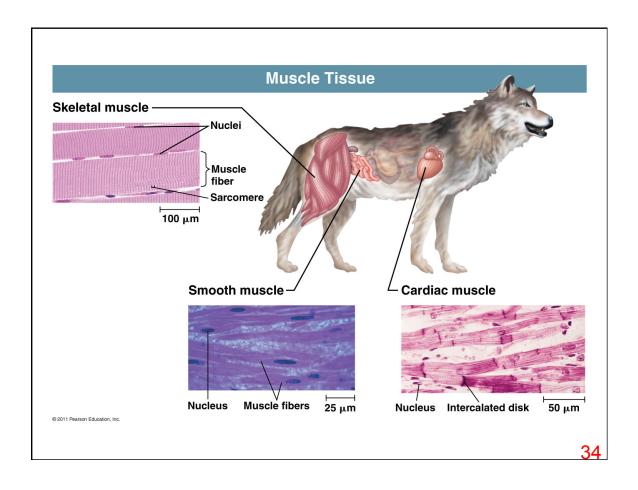

Calls destined to become red blood cells

Cancellous bone (red marrow)

Marrow cavity (yellow marrow)

TABLE 4.14	Comparison of Muscle Types	:	
	Skeletal Muscle	Cardiac Muscle	Smooth Muscle
Location	Attached to bones	Heart	Walls of hollow organs, blood vessels, eyes, glands, skin
Cell Shape	Very long, cylindrical cells (1–4 cm and may extend the entire length of the muscle; 10–100 µm in diameter)	Cylindrical cells that branch (100–500 µm in length; 12–20 µm in diameter)	Spindle-shaped cells (15–200 μm in length; 5–8 μm in diameter)
Nucleus	Multinucleated, peripherally located	Single, centrally located	Single, centrally located
Striations	Yes	Yes	No
Control	Voluntary (conscious)	Involuntary (unconscious)	Involuntary (unconscious)
Ability to Contract Spontaneously	No	Yes	Yes
Function	Body movement	Contraction provides the major force for moving blood through the blood vessels.	Movement of food through the digestive tract, emptying of the urinary bladder, regulation of blood vessel diameter, change in pupil size, contraction of many gland ducts, movement of hair, and many more functions
Special Features		Branching fibers, intercalated disks containing gap junctions joining the cells to each other	Gap junctions
